

# Graphic Lasso: Possible Accuracy for Multi-Layer Model

## 1 Discussion about Identifiability

Suppose we have a dataset with  $p$  variables and  $K$  categories. In multi-layer model, we assume the rank of decomposition  $r$  is known, and the precision matrices are of form

$$\Omega^k = \Theta_0 + \sum_{l=1}^r u_{lk} \Theta_l, \quad \text{for } k = 1, \dots, K. \quad (1)$$

The identifiability problem for  $\{\Theta_0, \Theta_1, \dots, \Theta_r, \mathbf{u}_1, \dots, \mathbf{u}_r\}$  is actually an identifiability problem for tensor decomposition.

Let  $\mathcal{Y} \in \mathbb{R}^{p \times p \times K}$  denote the collection of  $K$  networks, where  $\mathcal{Y}[:, :, k] = \Omega^k, k \in [K]$ . Let  $\mathcal{C} \in \mathbb{R}^{p \times p \times (r+1)}$  denote the collection of “core” networks, where  $\mathcal{C}[:, :, 1] = \sqrt{K} \Theta_0, \mathcal{C}[:, :, l] = \Theta_{l-1}, l = 2, \dots, (r+1)$ . Let  $\mathbf{U} \in \mathbb{R}^{K \times (r+1)} = (\mathbf{u}_0, \mathbf{u}_1, \dots, \mathbf{u}_r)$  denote the factor matrix, where  $\mathbf{u}_0 = \mathbf{1}_K / \sqrt{K}$ . Rewrite the model (1) in tensor form.

$$\mathcal{Y} = \mathcal{C} \times_3 \mathbf{U}. \quad (2)$$

Therefore, the identifiability problem for  $\{\Theta_l, \mathbf{u}_l\}$  becomes the identifiability problem for  $\{\mathcal{C}, \mathbf{U}\}$ . Before we discuss the identifiable condition case by case, we first assume  $\mathcal{C}$  is full rank on mode 3.

### 1. No sparsity constrain on $\mathbf{U}$ .

**Proposition 1.** *The decomposition  $\mathcal{C}$  and  $\mathbf{U}$  are identifiable if  $\mathbf{U}$  is an orthonormal matrix, i.e.,  $\mathbf{U}^T \mathbf{U} = \mathbf{I}_{r+1}$ .*

*Proof.* Let  $\text{Unfold}(\cdot)$  denote the unfold representation of a tensor on mode 3. The model (2) is equal to

$$\text{Unfold}(\mathcal{Y}) = \mathbf{U} \text{Unfold}(\mathcal{C}).$$

By matrix SVD, we have  $\text{Unfold}(\mathcal{Y}) = \tilde{\mathbf{U}} \Sigma \mathbf{V}^T$ , where  $\tilde{\mathbf{U}}$  is an orthonormal matrix. The SVD decomposition is unique up to orthogonal rotation (ignore row permutation).

Note that  $\mathbf{u}_0 = \mathbf{1}_K / \sqrt{K}$ . There always has a unique orthonormal matrix  $\mathbf{R}$  such that the first column of  $\tilde{\mathbf{U}} \mathbf{R}$  is equal to  $\mathbf{1}_K / \sqrt{K}$ . Let  $\mathbf{U} = \tilde{\mathbf{U}} \mathbf{R}$  and  $\text{Unfold}(\mathcal{C}) = \mathbf{R}^T \Sigma \mathbf{V}$ . Then,  $\mathbf{U}$  and  $\mathcal{C}$  are identifiable.  $\square$

### 2. Membership constrain on $\mathbf{U}$ . (Without intercept $\Theta_0$ )

If  $\mathbf{U}$  is a membership matrix, we are clustering  $K$  categories into  $r$  groups. Then, the model (1) becomes

$$\Omega^k = \Theta_{i_k}, \quad \text{for } k = 1, \dots, K,$$

where  $i_k \in [r]$  is the group for the  $k$ -th category. Then, let  $\mathcal{C} \in \mathbb{R}^{p \times p \times r}$ , where  $\mathcal{C}[:, l] = \Theta_l, l = 1, \dots, r$ , and  $\mathbf{U} \in \mathbb{R}^{K \times r} = (\mathbf{u}_1, \dots, \mathbf{u}_r)$

**Proposition 2.** *The decomposition  $\mathcal{C}$  and  $\mathbf{U}$  are identifiable up to permutation if  $\mathbf{U}$  is a membership matrix, i.e., in each row of  $\mathbf{U}$  there is only 1 copy of 1 and massive 0.*

*Proof.* If  $\mathbf{U}$  is a membership matrix, the model (2) is a special case of tensor block model. By Proposition 1 in Wang, the matrix  $\mathbf{U}$  is identifiable if  $\mathcal{C}$  is irreducible on mode 3. In our case, we assume  $\mathcal{C}$  is full rank on mode 3, and thus  $\{\mathbf{U}, \mathcal{C}\}$  are identifiable.  $\square$

**Remark 1.** The sparsity of  $\Theta_l$  won't affect the identifiability in this two cases. In no sparsity constrain case, we only need the full rankness of  $\text{Unfold}(\mathcal{C})$ , and the sparsity on the first and second mode of  $\mathcal{C}$  does not affect the rank of mode 3 unfolded matrix. In membership constrain, we only need mode 3 irreducible of  $\mathcal{C}$ .

**Remark 2.** The two cases discussed above are two extreme cases. Intermediate cases include the fuzzy clustering, where  $\sum_{l=1}^r u_{lk} = 1, k \in [K]$ , and the sparsity constrain for the column, where  $|\mathbf{u}_l|_0 < a, l \in [r]$ .

## 2 A simple extension

Let  $Q(\Omega) = \text{tr}(S\Omega) - \log |\Omega|$ . Assume the rank of decomposition  $r$  is known. Consider the constrained optimization problem

$$\begin{aligned} \min_{\mathcal{C}} \quad & \sum_{k=1}^K [Q(\Omega^k)] \\ \text{s.t.} \quad & \Omega^k = \Theta_0 + \sum_{l=1}^r u_{lk} \Theta_l, \quad \text{for } k = 1, \dots, K, \\ & \|\Theta_l\|_0 \leq b, \quad \text{for } l = 1, \dots, r, \\ & \|\Theta_0\|_0 \leq b_0, \\ & \mathbf{u}_l^T \mathbf{u}_l = 1, \quad \text{for } l = 1, \dots, r, \\ & \mathbf{u}_k^T \mathbf{u}_l = 0, \quad \text{for } k \neq l. \end{aligned}$$

where  $a, b, b_0$  are fixed positive constants,  $|\cdot|_0$  refers to the vector  $L_0$  norm, and  $\|\cdot\|_0$  refers to the matrix  $L_0$  norm. For simplicity, let  $\hat{\mathcal{C}} = \{\hat{\Theta}_0, \hat{\Theta}_1, \dots, \hat{\Theta}_r, \hat{\mathbf{u}}_1, \dots, \hat{\mathbf{u}}_r\}$  denote the estimation, and  $\hat{\Omega}^k = \hat{\Theta}_0 + \sum_{l=1}^r \hat{u}_{lk} \hat{\Theta}_l$  for  $k = 1, \dots, K$ .

For true precision matrices  $\Omega^k$ , let  $T^k = \{(j, j') | \omega_{j,j'}^k \neq 0\}$  and  $q^k = |T^k|$ . Let  $T = T^1 \cup \dots \cup T^K$  and  $q = |T|$ .

**Theorem 2.1.** *Suppose two assumptions hold. Let  $\{\Omega^k\}$  denote the true precision matrices. For the estimation  $\hat{\mathcal{C}}$  such that  $\sum_{k=1}^K [Q(\hat{\Omega}^k)] \leq \sum_{k=1}^K [Q(\Omega^k)]$  and satisfies the constrains, the following accuracy bound holds with probability tending to 1.*

$$\sum_{k=1}^K \left\| \hat{\Omega}^k - \Omega^k \right\|_F = \mathcal{O}_p \left[ \left\{ \frac{(p+q) \log p}{n} \right\}^{1/2} \right].$$

*Proof.* Let  $\Omega^k$  denote the true precision matrices for  $k = 1, \dots, K$ . Consider the estimation  $\hat{\mathcal{C}}$  such that  $\sum_{k=1}^K [Q(\hat{\Omega}^k)] \leq \sum_{k=1}^K [Q(\Omega^k)]$ . Let  $\Delta^k = \hat{\Omega}^k - \Omega^k$ . Define the function

$$G(\{\Delta^k\}) = \sum_{k=1}^K \text{tr}(S(\Omega^k + \Delta^k)) - \text{tr}(\Omega^k) - \log |\Omega^k + \Delta^k| + \log |\Omega^k| = I_1 + I_2,$$

where

$$I_1 = \sum_{k=1}^K \text{tr}((S^k - \Sigma^k)\Delta^k), \quad I_2 = \sum_{k=1}^K (\tilde{\Delta}^k)^T \int_0^1 (1-v)(\Omega^k + v\Delta^k)^{-1} \otimes (\Omega^k + v\Delta^k)^{-1} dv \tilde{\Delta}^k.$$

With probability tending to 1, we have

$$I_1 \leq C_1 \left( \frac{\log p}{n} \right)^{1/2} \sum_{k=1}^K (|\Delta_{T^k}^k|_1 + |\Delta_{T^{k,c}}^k|_1) + C_2 \left( \frac{p \log p}{n} \right)^{1/2} \sum_{k=1}^K \|\Delta^k\|_F, \quad I_2 \geq \frac{1}{4\tau_2^2} \sum_{k=1}^K \|\Delta^k\|_F^2.$$

Note that  $|\Delta_{T^k}^k|_1 \leq q^{1/2} \|\Delta^k\|_F$ . Then, we only need to deal with  $|\Delta_{T^{k,c}}^k|_1$ . Rewrite the term, we have

$$|\Delta_{T^{k,c}}^k|_1 = |\hat{\Theta}_{0,T^{k,c}} + \hat{u}_{1k}\hat{\Theta}_{1,T^{k,c}} + \dots + \hat{u}_{rk}\hat{\Theta}_{r,T^{k,c}}|_1 \leq (b_0 + rb) \|\Delta^k\|_{\max} \leq (b_0 + rb) \|\Delta^k\|_F.$$

Then, by Guo et al, we have

$$\sum_{k=1}^K \|\Delta^k\|_F = \sum_{k=1}^K \|\hat{\Omega}^k - \Omega^k\|_F = \mathcal{O}_p \left[ \left\{ \frac{(p+q) \log p}{n} \right\}^{1/2} \right]. \quad (3)$$

□

**Remark 3.** Note that  $q$  can be replaced by  $\max_k q^k$ , where  $q^k \leq (b_0 + rb)$  for all  $k = 1, \dots, K$ . Also, the accuracy (3) holds when  $q^k$  are fixed. Otherwise, the accuracy is of order  $\mathcal{O}_p \left[ q \left\{ \frac{\log p}{n} \right\}^{1/2} \right]$ .

**Remark 4.** This proof does not utilize the special structure of  $\Omega^k$ . We can go through the proof with the constrain  $|\Omega^k| < s$ .

### 3 Next

- Think about the identifiability of the intermediate cases (sparse matrix factorization).
- Think about the proof which utilizes the special structure of the  $\Omega^k$ .
